HIGHLIGHTS

The KANSAS AGRICULTURAL STATISTICS SERVICE July forecast of 453.6 million bushels represented an expected harvest of 8.1 million acres of wheat with an average of 56 bushels per acre yield, an increase of 19 bushels per acre over the previous year. If this yield was achieved, it would be a record yield for Kansas.

The cumulative disease loss estimate for the 2016 wheat crop was 13.1 percent or 68.4 million bushels. The potential yield of the crop without diseases was calculated at 522.0 million bushels, or 64.4 bushels per acre.

In 2016, Kansas wheat producers’ yields and test weights were decreased as a result of disease pressure. The most important diseases in 2016 were stripe rust (9.1% loss), leaf rust (1.3% loss), and barley yellow dwarf virus (1.3% loss). All crop reporting districts had significant losses but severity of loss varied slightly between districts.

Peaks and valleys correlated with weather patterns and disease epidemics mark loss estimates and are based on data collected yearly since 1976 (Figure 1). 2016 was an average year for wheat disease.
DISEASES

The most important disease of 2016 was **stripe rust**. This year saw a drastic decrease in estimated yield loss due to stripe rust compared to 2015 (15.4%) at 9.1%, but was still well above the 5-, 10-, and 20-year averages (6.05%, 4.08%, and 3.34% respectively). Stripe rust was favored by cool temperatures and frequent rainfall in 2016. Many of the most common wheat varieties are susceptible to stripe rust and this increases the risk of severe yield losses. Fortunately, many growers anticipated the treat of stripe rust and responded with foliar fungicide applications to combat the disease. This use of fungicide explains the lower yield loss in 2016 relative to 2015. Stripe rust caused a loss of 45.6 million bushels of wheat statewide in 2016.

Stripe rust caused yield loss in all the crop reporting districts in 2016. In susceptible varieties the minimum estimated yield loss was 6% and the maximum was 20% (Figure 2). The losses were lower in the western production districts where the dry conditions are more common. The wide-spread use of fungicides in western Kansas also offset potential yield losses in these key wheat producing regions of the state.
Leaf rust was the second most important disease this year, despite causing a much lower estimated loss than stripe rust (1.3%). This was a below-average year for leaf rust for the eighth year in a row compared to the 10- and 20-year averages of 2.38% and 2.13% respectively. The five-year average was 0.56%. Disease severity ranged around 10% and incidence varied but was around 20% statewide. Leaf rust was of most concern in western and central districts, reaching as much as 4% estimated loss. It was not commonly found in the eastern districts, possibly in part due to 55.2% of the acreage planted in eastern Kansas being planted to Everest, a variety resistant to leaf rust. An estimated total of 6.2 million bushels were lost to leaf rust in 2016.

Barley yellow dwarf was also disease of concern in 2016 and resulted in a statewide yield loss of 1.3% or 5.9 million bushels. This was an above-average year for barley yellow dwarf, as the 5-, 10-, and 20-year averages all fall below 1%. Barley yellow dwarf was most damaging in the western and central Kansas this year and was less prevalent in the eastern districts.

Other diseases of interest in 2016 were tan spot (0.9% estimated loss) and Septoria complex (0.3% estimated loss). In addition, flag smut, which resurfaced in 2015 after not having been seen for over 70 years, was detected again this year. The flag smut was present at trace levels in 12 counties in western and central Kansas, including four new county records: Ellsworth, Clay, Decatur, and Pawnee counties. A Karnal bunt survey was also conducted post-harvest in 2016. Karnal bunt was not detected in Kansas. This survey has been conducted yearly since 1993 with no positive finds.

Lesion nematode data were not collected in 2016 but data collection will resume in 2017.
The yield loss table from the last 20 years (Figure 3) shows that each year is unique. Weather, crop rotation, variety selection, and cultural practices all can affect disease severity and loss due to changes in disease from one year to the next. Stripe rust is currently the most important disease of wheat in Kansas, with a 9.1% estimated loss in 2016 and the highest 5-, 10-, and 20-year averages of any disease. It has surpassed leaf rust as the most important disease of Kansas.

Figure 3. Yield loss estimates from Kansas production 2008-2016 with 5-, 10-, and 20-year averages.

- Estimates were prepared by Kansas State University, Kansas Department of Agriculture, and USDA-ARS personnel. Estimates are based on expert opinions, not statistically designed.
- Estimates use a disease survey, variety resistance, variety acreages, crop district yield estimates, and loss functions for each disease. NASS/Kansas Agricultural Statistics provided information for variety acreages and crop district yield estimates.
- Special thanks to the staff at the Great Plains Diagnostic Laboratory, Kansas State University, and the Plant Protection & Weed Control program, Kansas Department of Agriculture, for their aid in surveying and disease diagnosis. Without their contributions, this paper would not be possible.
Lesion nematode estimates were begun in 2008-2010. The 2010 estimate is an average based upon 3 years of sampling. In total, over 2100 fields at a rate of 1 location/sample (2-3 acres) per 4800 acres of planted production acreages per county (NASS) were taken over the three-year period. After 2010, a preservation survey based upon a small number of samples (25-30/state annually) has been used for loss estimates to extend the 2008-2010 foundation survey. No data were collected in 2016 but collection will resume in 2017.
